Date	4-October- 2026
TeamID	6ab467fd0fc666a751b4124b
ProjectName	Auto Ticket Classification using Flow Designer
Maximum Marks	3 Marks

TEST CASES

1. Testing Objective

The objective of testing is to verify that the Auto Classify School IT Tickets flow correctly identifies newly created IT support incidents, assigns the expected Category and Subcategory, updates the Incident Workflow record, and sends the configured email notification to the caller.

2. Test Case Matrix

Test ID	Test Scenario / Input	Expected Result	Validation
TC-01	WiFi not working in library	Category = Network; Subcategory = Wi-Fi; confirmation email is generated.	Core documented test
TC-02	Projector not turning on	Category = Hardware; Subcategory = Projector; confirmation email is generated.	Core documented test
TC-03	Forgot password / login issue	Category = Access; Subcategory = Forgot Password.	Flow branch to be verified
TC-04	Slow or hanging computer	Category = Performance; Subcategory = Slow Computer.	Flow branch to be verified
TC-05	Check notification after classification	Email is available for the caller with the configured confirmation subject.	Notification validation
TC-06	Mandatory field validation	Required ticket information is captured before submission.	Data validation
TC-07	Auto-number validation	A unique incident number is generated for the new record.	Data validation
TC-08	Reference field validation	Caller, Assigned Group and Assigned to reference values resolve correctly.	Reference validation

3. Test Procedure

- Create an Incident Workflow record and enter the caller and Short Description.
- Save the record so that the Record Created trigger can execute.
- Check the Category and Subcategory values after the flow runs.
- Open the ticket and verify that the classification is stored in the record.
- Open System Logs → Emails and verify the notification for the caller.
- Repeat the procedure for the different issue descriptions.

4. Classification Rules Under Test

The project uses the documented keyword mapping: WiFi or Network → Network / Wi-Fi; Projector → Hardware / Projector; Password or Login → Access / Forgot Password; and Slow or Hanging → Performance / Slow Computer.

5. Acceptance Criteria

• The newly created ticket activates the flow when Category is empty.

• The correct Category is selected from the Short Description.

• The correct dependent Subcategory is stored.

• The Update Record action writes the classification to the incident.

• The caller receives the configured email notification.

• The incident number is generated correctly.

• Reference fields resolve to the appropriate records.

• The classification process is consistent across repeated test executions.

6. Test Evidence to Capture

For each executed test, capture a screenshot of the created incident, the resulting Category and Subcategory, and the email notification where applicable. Evidence should be stored in the project Testing folder and named using the corresponding Test ID.

7. Testing Mechanism of Working

Testing follows an input-process-output approach. The tester supplies a known issue description, Flow Designer processes the newly created record, the keyword branch determines the classification, the Update Record action stores the result, and the notification action communicates completion. The observed result is then compared with the expected result in the test case matrix.

8. Test Case Conclusion

The test cases provide a structured method for validating the complete ticket-classification workflow. The two core scenarios documented in the project are WiFi and Projector. The Password/Login and Slow/Hanging scenarios correspond to configured flow branches and should be executed and evidenced in the target ServiceNow instance before final submission.
