Date	4-October- 2026
TeamID	6ab467fd0fc666a751b4124b
ProjectName	Auto Ticket Classification using Flow Designer
Maximum Marks	3 Marks

TEST RESULTS

1. Test Result Summary

The project source documents successful end-to-end validation for the WiFi and Projector scenarios. The WiFi scenario produced Network / Wi-Fi classification and an email notification. The Projector scenario produced Hardware / Projector classification and an email notification. These are the documented observed results. The other configured branches require execution in the actual ServiceNow instance before they can be recorded as passed.

Test ID	Scenario	Expected	Documented / Execution Status
TC-01	WiFi not working in library	Network / Wi-Fi + email	PASS – documented result
TC-02	Projector not turning on	Hardware / Projector + email	PASS – documented result
TC-03	Forgot password / login	Access / Forgot Password	To be executed
TC-04	Slow or hanging computer	Performance / Slow Computer	To be executed
TC-05	Email notification check	Caller receives configured email	PASS for documented TC-01/TC-02
TC-06	Mandatory field validation	Required information captured	Validation required
TC-07	Auto-number validation	Unique incident number	Validation required
TC-08	Reference fields	Correct user/group references	Validation required

2. Documented WiFi Result

In the documented WiFi test, the Short Description was 'WiFi not working in library'. After the flow executed, Category was shown as Network and Subcategory as WiFi. The source also records that an email was sent to the caller and could be located under System Logs → Emails.

3. Documented Projector Result

In the documented Projector test, the Short Description was 'Projector not turning on'. The flow classified the ticket as Hardware with Projector as the Subcategory. The source also records the

corresponding email notification.

4. Result Interpretation

The documented results demonstrate that the main automation path works for the WiFi and Projector examples: a ticket is created, the keyword condition is matched, Category and Subcategory are updated, and the caller notification is generated. This confirms the core Flow Designer mechanism for the two recorded scenarios.

5. Additional Result Validation

The flow configuration also contains branches for Password/Login and Slow/Hanging computer descriptions. Because the source material does not provide observed pass results for those branches, they should be executed separately and marked Pass only after the expected Category and Subcategory values are observed in the ServiceNow instance.

6. Notification Validation

The notification is validated by opening System Logs → Emails after ticket creation and checking the email generated for the caller. The project uses a configured confirmation subject and the recipient is Caller → Email.

7. Overall Testing Conclusion

The available documented evidence supports successful testing of the WiFi and Projector classification scenarios and their notification steps. The test result record should remain evidence-based: configured branches without observed execution should be treated as pending validation rather than automatically marked as passed.

8. Recommended Evidence

- Screenshot of the WiFi incident showing Network / Wi-Fi.
- Screenshot of the Projector incident showing Hardware / Projector.
- Screenshot of the generated caller email.
- Screenshot of the Password/Login test after execution.
- Screenshot of the Slow/Hanging test after execution.
- Screenshot showing the active Auto Classify School IT Tickets flow.

9. Final Result

The Auto Ticket Classification using Flow Designer project demonstrates that rule-based classification can reduce manual ticket handling and provide consistent Category/Subcategory values. The documented WiFi and Projector tests provide the confirmed baseline results, while the remaining test cases provide the validation checklist for complete project acceptance.
