FINAL PROJECT REPORT

Auto Ticket Classification using Flow Designer

This report presents the complete project documentation for a ServiceNow-based no-code automation that classifies school IT helpdesk tickets. The project focuses on automating Category and Subcategory assignment from the Short Description of newly created incident records and notifying the caller after classification.

1. Introduction

School IT helpdesks receive a large number of requests from students and teachers. Common requests include Wi-Fi connectivity problems, projector failures, password or login issues, and slow or hanging computers. When classification is performed manually, support staff must repeatedly read each request and select appropriate values.

The project proposes Flow Designer as a simple automation mechanism. A newly created Incident Workflow record is evaluated when Category is empty. The flow uses predefined keyword conditions to classify the request and update the record.

FINAL PROJECT REPORT – REQUIREMENTS AND DESIGN

2. Requirements

The solution requires a structured Incident Workflow table with Number, Caller, Category, Subcategory, Short Description, Description, State, Assigned Group and Assigned to. Number is generated automatically, while reference fields connect the record to appropriate users or groups.

2.1 Functional Requirements

- Create and store IT incident requests.
- Automatically classify incidents from the Short Description.
- Assign Category and dependent Subcategory.
- Send a confirmation email to the caller.
- Support testing and validation of classification rules.

2.2 Classification Requirements

The documented mapping is WiFi / Network → Network / Wi-Fi; Projector → Hardware / Projector; Password / Login → Access / Forgot Password; and Slow / Hanging → Performance / Slow Computer.

3. Project Design

The architecture consists of the caller, Incident Workflow table, Flow Designer automation, classification rules, record update and email notification. The flow is named Auto Classify School IT Tickets.

3.1 Trigger and Condition

The trigger is Record Created on the Incident Workflow table. The documented condition is Category is Empty, ensuring that the automation acts on records requiring classification.

FINAL PROJECT REPORT – DEVELOPMENT

4. Development

4.1 Update Set

A Project Update Set is used to collect the project configuration. The update set is created under Local Update Sets, kept In progress during development, and made the current set before configuration work is performed.

4.2 Incident Workflow Table

The Incident Workflow table is configured with the required fields and Auto Number. Form fields include Caller, Category, Subcategory, Short Description, Description, State, Assigned Group and Assigned to.

4.3 Dependent Choices

Subcategory is configured as dependent on Category. The relationship ensures that the appropriate subcategory is available for the selected category.

4.4 Flow Designer

The Auto Classify School IT Tickets flow uses If / Else If branches. Each branch examines the Short Description and uses Update Record to write the appropriate Category and Subcategory.

4.5 Notification

After classification, the Send Email action uses Caller → Email as the recipient. The notification confirms that the request has been submitted.

5. Mechanism of Working

The complete mechanism is: Record Created → Category is Empty → Short Description keyword analysis → matching classification branch → Update Record → caller email notification.

FINAL PROJECT REPORT – TESTING

6. Testing

Testing verifies whether the automation produces the expected classification and notification. The project documentation records two completed core scenarios and identifies additional branches for validation.

6.1 WiFi Test

The documented WiFi scenario uses 'WiFi not working in library'. The expected and documented result is Category = Network and Subcategory = WiFi, with an email notification to the caller.

6.2 Projector Test

The documented Projector scenario uses 'Projector not turning on'. The expected and documented result is Category = Hardware and Subcategory = Projector, with an email notification.

6.3 Additional Tests

Password/Login and Slow/Hanging branches are configured in the flow. They should be executed in the target ServiceNow environment and marked as passed only after the expected Category and Subcategory values are observed.

6.4 Evidence

- Capture the created incident and classification values.
- Capture the generated email under System Logs → Emails.
- Capture the active Flow Designer configuration.
- Capture additional branch results before final acceptance.

FINAL PROJECT REPORT – DEPLOYMENT AND DOCUMENTATION

7. Deployment

After development and validation, the Project Update Set is moved to Complete. The documented procedure provides an Export to XML option so the configuration can be transferred to another environment.

8. User Operation

A user creates an Incident Workflow record and provides the caller and Short Description. The system performs classification automatically. The user does not need to manually select the classification when the configured keyword rule matches the request.

9. Demonstration Procedure

- Open the ServiceNow environment.
- Open the Incident Workflow form.
- Create a test incident.
- Enter a classification keyword in Short Description.
- Save the record.
- Verify Category and Subcategory.
- Verify the caller email.
- Open Flow Designer and show the automation.

10. Project Benefits

- Reduced manual classification effort.
- More consistent ticket data.
- Faster and repeatable classification.
- Automatic caller acknowledgement.
- No-code implementation that is easier to maintain.

FINAL PROJECT REPORT – CONCLUSION

11. Conclusion

Auto Ticket Classification using Flow Designer provides a structured approach to automating school IT helpdesk ticket classification. The project converts a repetitive manual activity into a rule-based workflow that uses the Short Description to determine Category and Subcategory.

The documented WiFi and Projector scenarios demonstrate the core workflow from ticket creation through classification and notification. The configured Password/Login and Slow/Hanging branches provide additional classification capabilities that should be validated with execution evidence in the target instance.

12. Future Extension

The project structure can support additional classification rules and automation actions as requirements grow. Any future extension should preserve the existing dependent Category/Subcategory relationship and validation process.

13. Final Deliverables

- Problem Statement and Ideation
- Requirements
- Architecture, Use Case and DFD
- Team Roles and Project Schedule
- Development Guide and Flow Logic
- Test Cases and Test Results
- README, Final Project Report and User Manual
- Demonstration materials

14. Final Statement

The project establishes a practical no-code foundation for consistent school IT ticket classification using ServiceNow Flow Designer. Its documented rules, testing approach, deployment procedure and user guidance provide a complete project lifecycle from problem identification to demonstration.
