# USER MANUAL

## Auto Ticket Classification using Flow Designer

### 1. Purpose

This user manual explains how to use and demonstrate the Auto Ticket Classification using Flow Designer solution. The manual is intended for users who create IT support requests and for support personnel who review the resulting classified tickets.

### 2. Before You Start

- Ensure the ServiceNow environment is available.
- Ensure the Auto Classify School IT Tickets flow is active.
- Ensure the Incident Workflow table and required fields are configured.
- Ensure the Category/Subcategory dependency is configured.

### 3. Create an IT Ticket

- Open the Incident Workflow form.
- Select or enter the Caller.
- Enter a clear Short Description of the issue.
- Add Description information if required.
- Save the record.

### 4. Classification Examples

- WiFi not working → Network / Wi-Fi
- Projector not turning on → Hardware / Projector
- Forgot password → Access / Forgot Password
- Computer slow or hanging → Performance / Slow Computer

# USER MANUAL – AUTOMATED CLASSIFICATION

## 5. What Happens After Saving

When the incident is created, the Flow Designer trigger checks whether Category is empty. If the condition is satisfied, the flow analyzes the Short Description. The matching If / Else If branch determines the Category and Subcategory, and Update Record stores the result.

## 6. Email Notification

After the classification update, the Send Email action sends a confirmation to Caller → Email. Administrators can inspect the generated email under System Logs → Emails.

## 7. Checking the Result

- Open the newly created ticket.
- Check the Category field.
- Check the Subcategory field.
- Verify that the values correspond to the issue description.
- Check the email log if notification verification is required.

## 8. Example: WiFi Ticket

Create a ticket with the Short Description 'WiFi not working in library'. After the flow executes, verify Network as Category and WiFi as Subcategory. Then verify the caller notification.

## 9. Example: Projector Ticket

Create a ticket with the Short Description 'Projector not turning on'. Verify Hardware as Category and Projector as Subcategory, followed by the caller notification.

# USER MANUAL – ADMINISTRATION AND TESTING

## 10. Administrator Checks

- Open Flow Designer and locate Auto Classify School IT Tickets.
- Verify the Record Created trigger.
- Verify Category is Empty condition.
- Review the keyword If / Else If branches.
- Verify Update Record actions.
- Verify Send Email recipient and subject.

## 11. Testing

Testing should use controlled descriptions representing each configured branch. The project documentation records successful WiFi and Projector scenarios. Password/Login and Slow/Hanging scenarios should be executed before final acceptance and supported with screenshots.

## 12. Troubleshooting

- If no classification occurs, check whether the flow is active.
- Check whether Category was already populated before the trigger condition was evaluated.
- Check whether the Short Description contains the configured keyword.
- Verify the Category/Subcategory choice and dependency configuration.
- Check System Logs → Emails for notification evidence.

## 13. Deployment Administration

Use the Project Update Set to package the configuration. During development keep it In progress. After validation, set it to Complete and use the documented XML export process when transferring the configuration.

# USER MANUAL – DEMONSTRATION CHECKLIST

## 14. Demonstration Steps

- Open the ServiceNow environment.
- Open the Incident Workflow form.
- Create a WiFi test ticket.
- Save and verify Network / Wi-Fi.
- Show the generated email notification.
- Create a Projector test ticket.
- Save and verify Hardware / Projector.
- Open Flow Designer and show the trigger and conditions.
- Show the Update Record actions.
- Show the Send Email action.
- Demonstrate additional Password/Login and Slow/Hanging branches if they have been validated.

## 15. User Responsibilities

Ticket creators should provide a clear Short Description because the automated classification depends on the configured keywords. IT support personnel should review the resulting classification and continue normal ticket handling after automation.

## 16. Expected User Experience

The intended experience is simple: the user submits a clear issue description, the system automatically determines the configured classification, the record is updated, and the caller receives confirmation. This reduces the need for manual category selection for supported issue types.

## 17. Safety and Accuracy Note

The automation is rule-based. If a description does not contain a configured keyword or does not match a supported branch, the system may not classify it as expected. Such tickets should be reviewed manually.

## 18. Conclusion

This manual provides the basic operating, validation, troubleshooting and demonstration procedures for the Auto Ticket Classification using Flow Designer project. It should be used together with the test cases and final project report.
