ProjectName	Auto Ticket Classification using Flow Designer
Maximum Marks	3 Marks

IDEATION DIAGRAM

IDEATION DIAGRAM – AUTO TICKET CLASSIFICATION USING FLOW DESIGNER

Core Idea: Automate ticket classification from keywords in the Short Description and automatically assign Category, Subcategory and caller notification.

Diagram Description

The ideation begins with the school IT helpdesk receiving incident requests from students, teachers, and staff. The main idea is to remove repetitive manual classification by using ServiceNow Flow Designer to examine the Short Description and identify the type of issue.

The proposed flow receives the incident, analyzes predefined keywords, and automatically assigns the appropriate Category and Subcategory. The documented mappings are WiFi → Network / Wi-Fi, Projector → Hardware / Projector, Password or Login → Access / Forgot Password, and Slow or Hanging → Performance / Slow Computer.

After classification, the ticket is stored in a structured form and an automated email notification is sent to the caller. This ideation therefore connects ticket creation, keyword analysis, classification, notification, and improved helpdesk handling into one simple no-code process.

1. Automation of Ticket Classification

The primary idea is to automate the classification of newly created IT support tickets. Instead of requiring an IT agent to inspect every request and manually select a category, Flow Designer evaluates the ticket description and performs the classification automatically.

2. Keyword-Based Classification

The flow uses predefined keywords in the Short Description. WiFi or Network indicates a Network issue, Projector indicates a Hardware issue, Password or Login indicates an Access issue, and Slow or Hanging indicates a Performance issue. This provides a simple and maintainable rule-based approach.

3. Accurate Category and Subcategory Mapping

The idea includes dependent choice logic so that Subcategory values correspond to the selected Category. This supports consistent data capture and reduces incorrect combinations during ticket processing.

4. Automatic Notification

After classification, the system sends an email notification to the caller. The notification confirms that the request has been submitted and improves communication without requiring a separate manual response from the helpdesk.

5. Reduced Manual Effort and Faster Routing

By automating repetitive classification activities, IT staff can spend less time reviewing basic requests. Consistent classification can also improve ticket routing and help the support team respond more efficiently.

6. Scalability and Maintainability

The solution is designed as a no-code Flow Designer implementation. Additional keywords, categories, subcategories, or automation actions can be introduced later as the helpdesk requirements grow. The source project identifies maintainability and future scalability as important business requirements.

Conclusion

The ideation for Auto Ticket Classification using Flow Designer converts a manual IT helpdesk process into an automated workflow. The concept focuses on keyword analysis, automatic classification, structured ticket data, caller notification, reduced manual effort, and a scalable ServiceNow implementation.
