ProjectName	**Auto Ticket Classification using Flow Designer**
Maximum Marks	3 Marks

PROBLEM STATEMENT

1. Background

The school IT helpdesk receives multiple incident requests every day from students and teachers. These requests commonly relate to Wi-Fi connectivity, projector failures, password or login problems, and slow or hanging computers. Each request must be reviewed by IT staff before it can be categorized and routed for appropriate support.

2. Existing Problem

At present, the classification of support tickets is performed manually. IT staff read the short description and other ticket information, identify the type of problem, and then select the appropriate Category and Subcategory. This repeated manual activity consumes staff time, introduces the possibility of inconsistent classification, and becomes difficult to manage when the number of support requests increases.

The uploaded project document identifies the manual review process as time-consuming, error-prone, and not scalable. In addition, the caller needs confirmation that the request has been received. Without automation, these activities depend heavily on the availability and attention of IT personnel.

3. Core Problem to be Addressed

The central problem is the lack of an automated mechanism to classify newly created IT support tickets from the information entered by the requester. A ticket describing a Wi-Fi issue should be classified as Network with the Wi-Fi Subcategory; a projector issue should be classified as Hardware with the Projector Subcategory; a password or login problem should be classified as

Access with the Forgot Password Subcategory; and a slow or hanging computer should be classified as Performance with the Slow Computer Subcategory.

4. Impact of the Existing Manual Process

Manual ticket classification increases the workload of IT support staff because every incoming request requires individual inspection and classification. As the volume of incidents grows, the same classification activity must be repeated for a larger number of tickets. Manual selection can also lead to incorrect or inconsistent Category and Subcategory values, which may affect subsequent ticket handling and reporting.

The project also needs a structured method for maintaining the relationship between Category and Subcategory. For example, Wi-Fi should be available under Network, Projector under Hardware, Forgot Password under Access, and Slow Computer under Performance. A dependent-choice configuration is therefore required so that the available Subcategory values correspond correctly to the selected Category.

5. Need for Automation

The project requires a simple and maintainable automation mechanism that can classify tickets immediately after creation. The proposed solution uses ServiceNow Flow Designer, a no-code approach described in the source document. The flow evaluates keywords in the Short Description and automatically updates the ticket with the appropriate Category and Subcategory.

The automation is also intended to reduce manual effort for IT agents, improve ticket-routing efficiency, and standardize ticket information. After classification, an email notification is sent to the caller to confirm that the request has been submitted. This provides a consistent acknowledgement without requiring manual communication from the helpdesk.

6. Proposed Problem Resolution

The proposed resolution is to implement an Auto Classify School IT Tickets flow in ServiceNow. The flow is triggered when a record is created in the Incident Workflow table and the Category is empty. It then evaluates the Short Description using predefined conditions and updates the record according to the matching issue type. The final step sends an email notification to the caller.

7. Project Objective

The objective is to provide a reliable, no-code and easily maintainable solution that automatically classifies school IT helpdesk incidents, reduces manual classification effort, improves consistency, and supports efficient ticket handling. The solution should also be scalable so that additional classification rules can be introduced in the future.

8. Expected Outcome

The expected outcome is an automated ticket-classification process in which newly created incidents are classified consistently, dependent Category and Subcategory values are maintained correctly, and callers receive an automated confirmation. The solution is intended to make the school IT helpdesk process faster, more standardized, and easier to maintain.
