ProjectName	Auto Ticket Classification using Flow Designer
Maximum Marks	3 Marks

ARCHITECTURE DIAGRAM

ARCHITECTURE DIAGRAM – AUTO TICKET CLASSIFICATION USING FLOW DESIGNER

Mechanism: Ticket Creation → Trigger → Keyword Analysis → Category/Subcategory Update → Record Storage → Email Notification

Figure 1: System Architecture for Auto Ticket Classification using Flow Designer

The architecture illustrates the end-to-end flow of an IT support request. A student or teacher creates an incident in the Incident Workflow table by entering the caller information and a short description. Flow Designer is triggered when the record is created and the Category field is empty. The flow analyzes the short description using predefined keyword conditions and updates the ticket with the appropriate Category and Subcategory.

1. Architecture Components

User / Caller: Students and teachers submit IT support requests. Incident Workflow: Stores the ticket information, including Number, Caller, Category, Subcategory, Short Description, Description, State, Assigned Group and Assigned to. Flow Designer: Provides the no-code automation and evaluates the predefined conditions. Classification Rules: Match keywords to the corresponding Category and Subcategory. Email Action: Sends an acknowledgement to the caller after classification.

2. Mechanism of Working

Ticket Creation – The caller creates a new IT support ticket with the required caller information and Short Description.

Flow Trigger – Flow Designer uses the Record Created trigger on the Incident Workflow table with the condition Category is Empty.

Keyword Analysis – The flow checks the Short Description using If / Else If conditions.

Classification – WiFi/Network is classified as Network/Wi-Fi; Projector as Hardware/Projector; Password/Forgot Password as Access/Forgot Password; and Slow Computer as Performance/Slow Computer.

Record Update – The Update Record action writes the Category and Subcategory values into the incident.

Email Notification – The Send Email action sends the configured confirmation message to Caller → Email.

3. Data Flow

The data moves from the caller to the Incident Workflow record, from the record to Flow Designer for keyword evaluation, and then back to the record through the Update Record action. After classification, the system sends the ticket confirmation to the caller. This creates a continuous automated process from submission to acknowledgement.

4. Benefits of the Architecture

The architecture reduces manual classification work, improves consistency of Category and Subcategory values, supports efficient ticket handling, provides automatic caller acknowledgement, and remains maintainable because the classification logic is implemented through Flow Designer rather than complex scripting.
