DATA FLOW DIAGRAM (DFD)

DATA FLOW DIAGRAM (DFD) – AUTO TICKET CLASSIFICATION

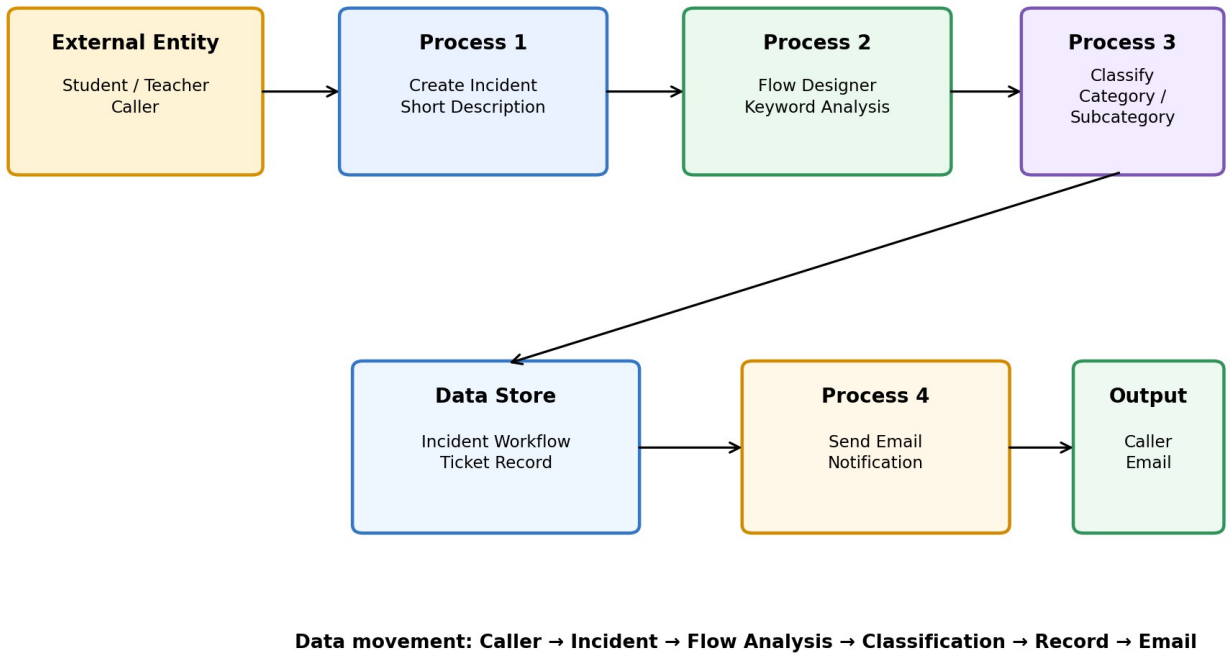

Figure 3: Data Flow Diagram for Auto Ticket Classification using Flow Designer

The DFD represents how ticket information moves through the project. A Student or Teacher provides the incident details. The incident is created in the Incident Workflow record, processed by Flow Designer, classified using keyword rules, stored as structured ticket data, and followed by an email notification to the caller.

1. External Entity

The Student or Teacher is the external source of the ticket data. The caller provides information such as Caller and Short Description.

2. Processes and Data Store

The first process creates the incident. The second process is Flow Designer keyword analysis. The third process classifies Category and Subcategory. The Incident Workflow record acts as the structured data store. The final process sends an email notification.

3. Data Flow

• Caller → Incident Creation: Short Description and caller information are submitted.

• Incident → Flow Designer: The newly created record is evaluated when Category is empty.

• Flow Designer → Classification: Keywords determine the issue category and subcategory.

• Classification → Incident Workflow: The Update Record action stores Category and Subcategory.

• Incident Workflow → Email: The Send Email action sends ticket confirmation to the caller.

4. Mechanism of Working

The DFD operates as a sequential flow of information. The ticket starts with the caller, passes through automated keyword analysis and classification, is stored in the Incident Workflow table, and ends with an acknowledgement email. The process reduces repetitive manual classification and keeps ticket data standardized.
