PROJECT DESIGN DESCRIPTION

PROJECT DESIGN – COMPONENT AND FLOW OVERVIEW

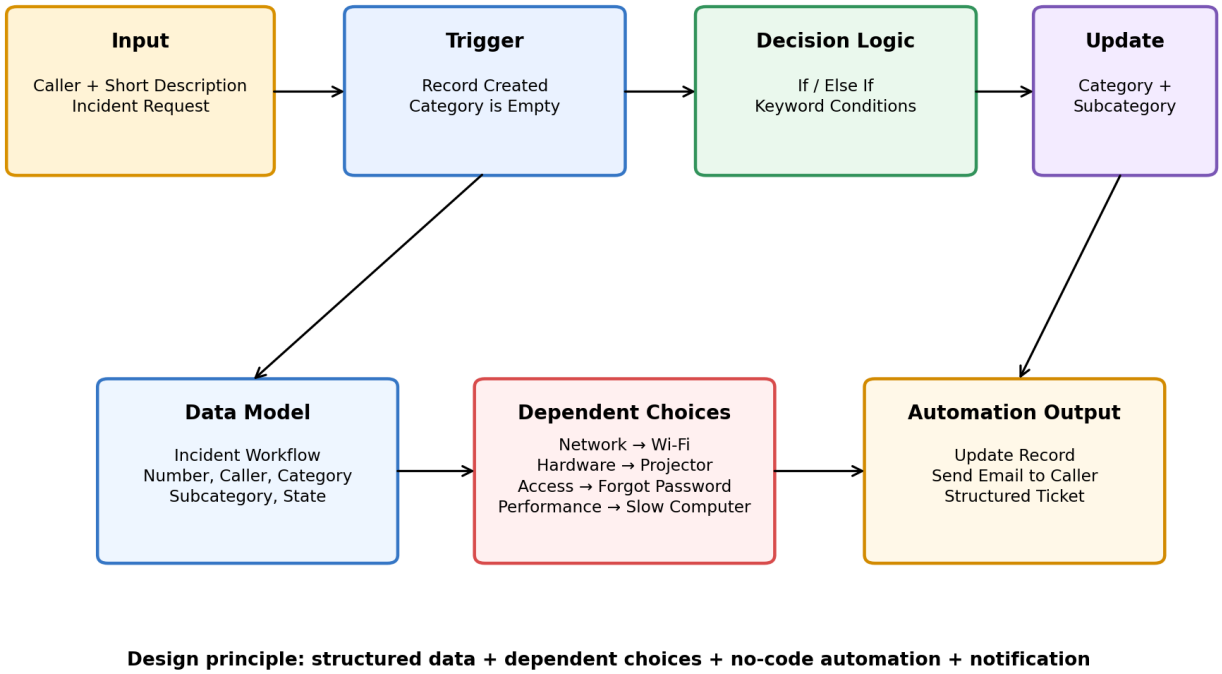

Figure 4: Project Design Overview for Auto Ticket Classification using Flow Designer

The design combines a structured Incident Workflow table, dependent choice configuration and a no-code Flow Designer automation. The flow starts with a newly created record, checks whether Category is empty, evaluates keywords and updates Category and Subcategory. After classification, the ticket can be stored consistently and the caller can receive an automated email.

1. Data Model Design

The Incident Workflow table contains Number, Caller, Category, Subcategory, Short Description, Description, State, Assigned Group and Assigned to. Number is an Auto Number, while Caller and assignment fields use references. Category, Subcategory and State use choice values.

2. Dependent Choice Design

Subcategory is configured as dependent on Category. The documented mappings are Wi-Fi → Network, Projector → Hardware, Forgot Password → Access, and Slow Computer → Performance. This keeps the available Subcategory values consistent with the selected Category.

3. Flow Design

The flow is named Auto Classify School IT Tickets. Its trigger is Record Created on the Incident Workflow table with Category is Empty as the condition. If/Else If branches inspect the Short Description and Update Record actions set the matching Category and Subcategory.

4. Mechanism of Working

- Create the Incident Workflow record.
- Trigger the flow when the record is created and Category is empty.
- Analyze the Short Description for predefined keywords.
- Set Category and Subcategory using Update Record.
- Maintain the structured ticket record.
- Send the configured email notification to Caller → Email.

5. Expected Design Benefits

The design reduces manual effort, improves classification consistency, supports efficient ticket handling, provides automatic acknowledgement and allows the classification rules to be maintained and extended through Flow Designer.
