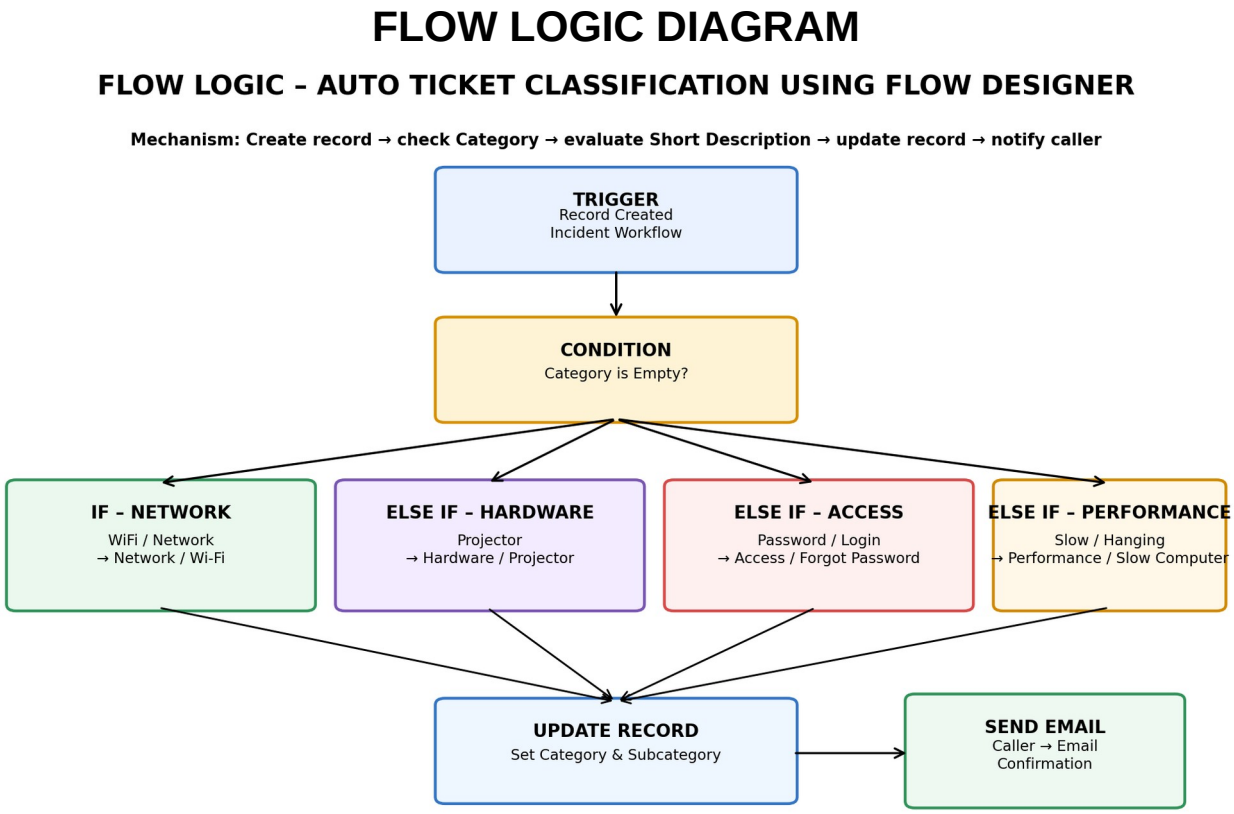

Figure 7: Flow Logic for Auto Ticket Classification using Flow Designer

The flow logic illustrates how the Auto Ticket Classification using Flow Designer process works from ticket creation to notification. When a new Incident Workflow record is created and the Category field is empty, the flow evaluates the Short Description using predefined keyword conditions. WiFi or Network issues are classified as Network with the Wi-Fi subcategory, Projector issues as Hardware with the Projector subcategory, Password or Login issues as Access with the Forgot Password subcategory, and Slow or Hanging issues as Performance with the Slow Computer subcategory. The Update Record action stores the selected Category and Subcategory, after which the Send Email action sends a confirmation notification to the caller.
