ProjectName	Auto Ticket Classification using Flow Designer
Maximum Marks	3 Marks

PROJECT DEMONSTRATION

Screen 1: Flow Designer – Main Configuration

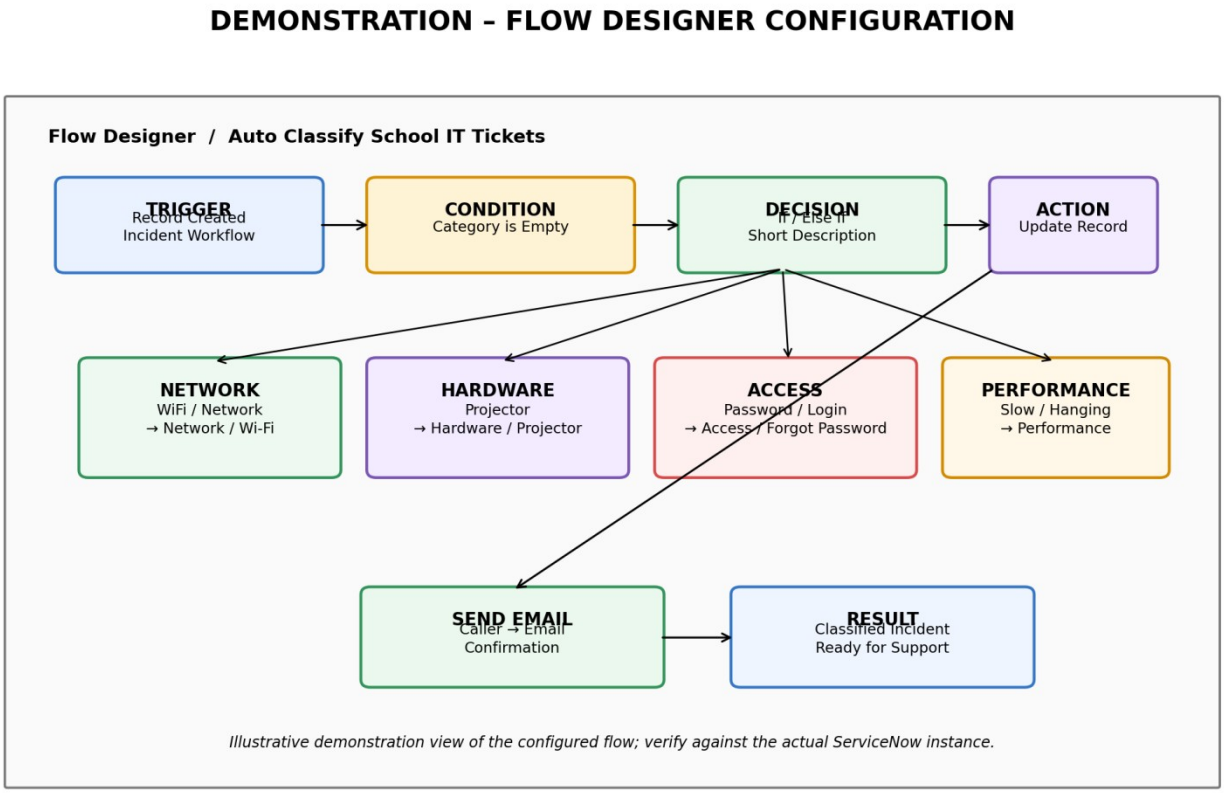

Figure 1: Flow Designer Configuration – Auto Classify School IT Tickets

This screen presents the main Flow Designer configuration for the Auto Ticket Classification project. The flow starts with a Record Created trigger on the Incident Workflow table, checks whether Category is empty, evaluates the Short Description through If/Else If conditions, updates the classification fields, and sends an email notification to the caller.

Demonstration Point

During the demonstration, show the flow name, trigger, condition, decision branches, Update Record action, and Send Email action in sequence.

DEMONSTRATION SCREEN 2

Screen 2: Flow Trigger and Classification Logic

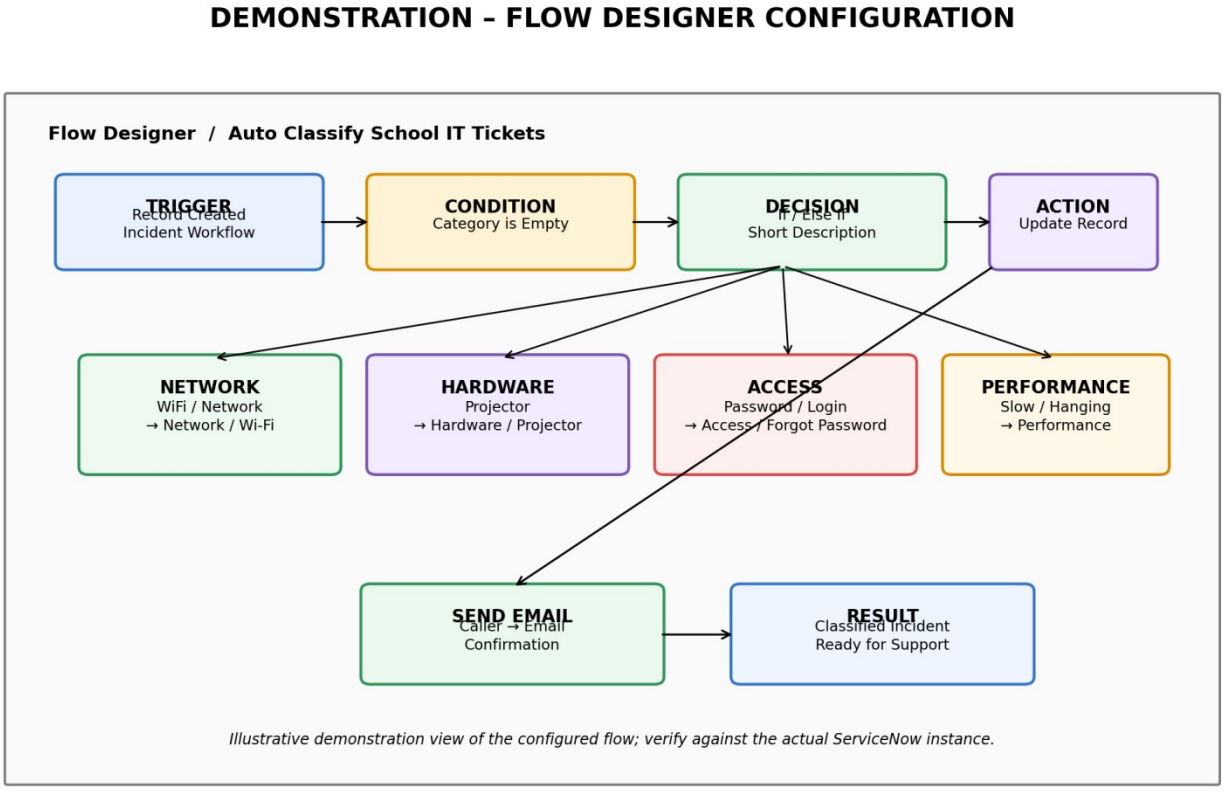

Figure 2: Flow Trigger, Condition and Classification Logic

The flow is activated when a new Incident Workflow record is created and the Category field is empty. The Short Description is then evaluated against the configured issue keywords. The classification branches represent Network/Wi-Fi, Hardware/Projector, Access/Forgot Password, and Performance/Slow Computer.

Mechanism of Working

The mechanism is: Record Created → Category is Empty → Keyword Analysis → Matching Branch → Update Record → Email Notification. This provides an automated path from ticket submission to classified incident.

DEMONSTRATION SCREEN 3

Screen 3: WiFi Test – Incident Input

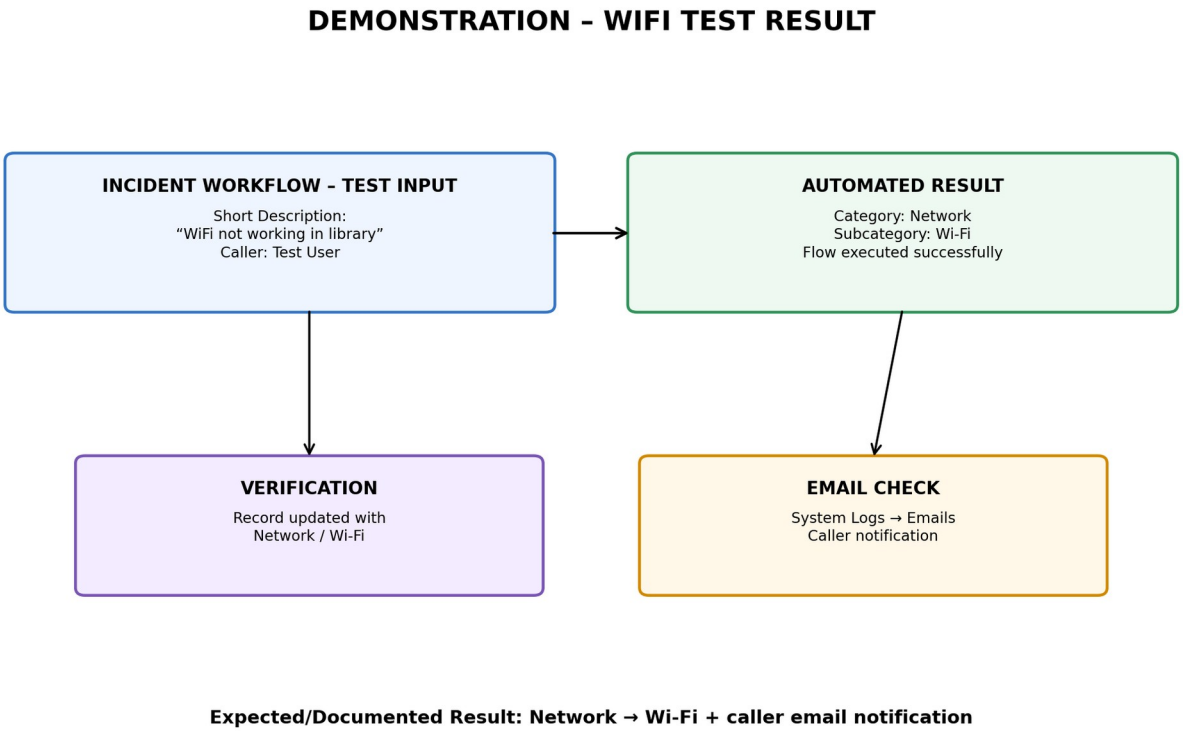

Figure 3: WiFi Test – Incident Input and Automated Classification

The WiFi demonstration uses the Short Description “WiFi not working in library.” The flow evaluates the description and applies the Network category with Wi-Fi as the Subcategory. The demonstration also verifies that the updated incident can be reviewed after the automation completes.

Verification Point

Show the original Short Description and then show the resulting Category and Subcategory. The documented project result is Network / Wi-Fi.

DEMONSTRATION SCREEN 4

Screen 4: WiFi Test – Notification Verification

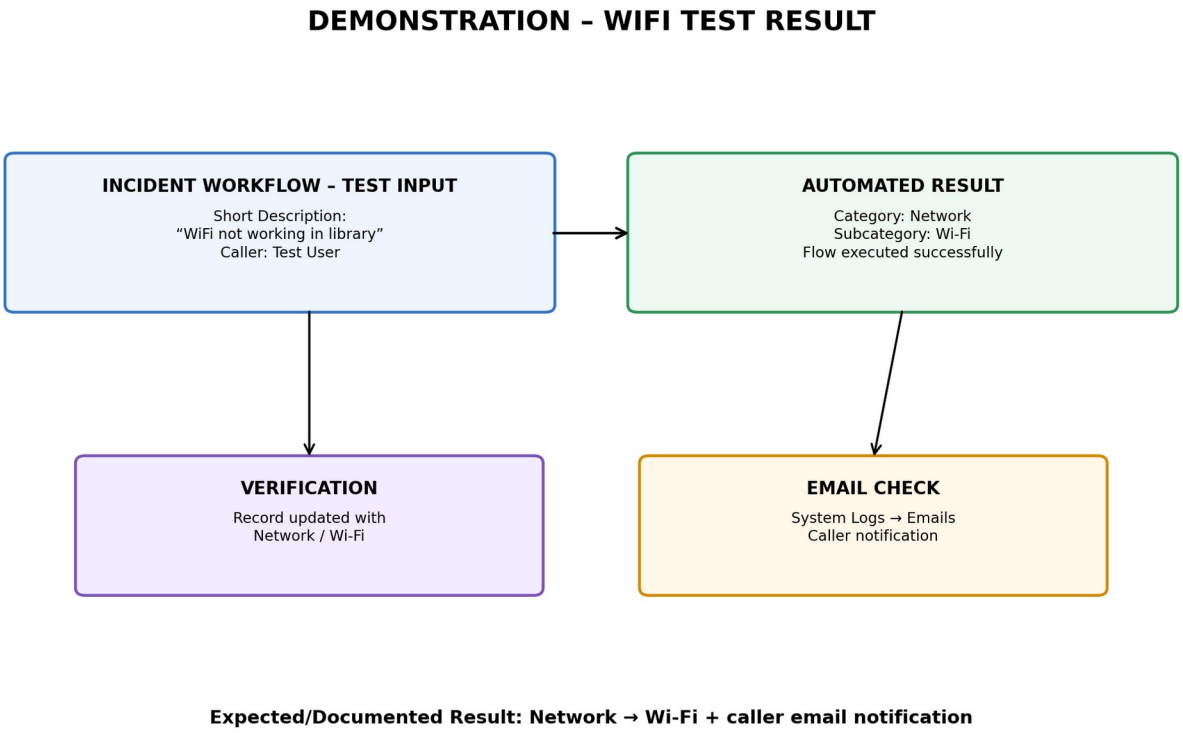

Figure 4: WiFi Test – Classification and Caller Notification

After the WiFi ticket is classified, the notification step is verified through the email log. The documented workflow sends a confirmation to the caller after the record is updated. This demonstrates the complete path from the WiFi incident description through classification and notification.

Demonstration Sequence

Create the WiFi incident → save the record → verify Network / Wi-Fi → open the email log → verify the caller notification.

DEMONSTRATION SCREEN 5

Screen 5: Projector Test – Incident Input

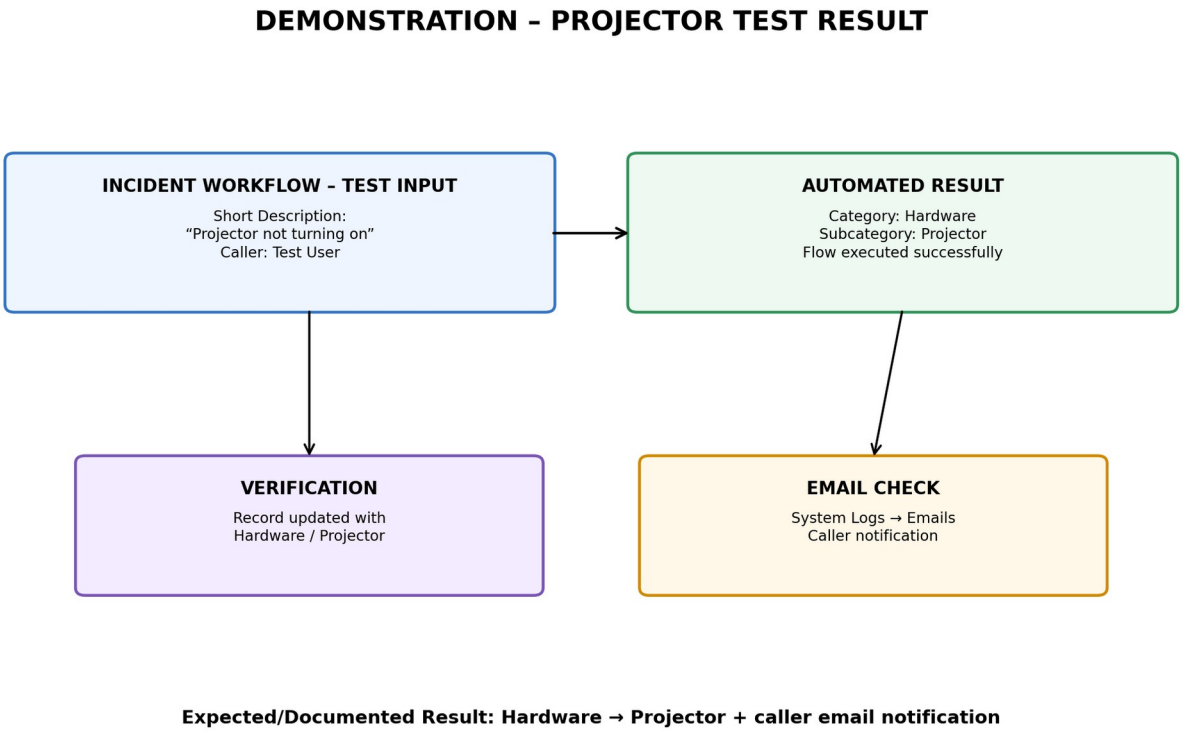

Figure 5: Projector Test – Incident Input and Automated Classification

The Projector demonstration uses the Short Description “Projector not turning on.” The configured flow identifies the Projector condition and assigns Hardware as the Category and Projector as the Subcategory. The resulting incident is then reviewed for correctness.

Verification Point

Show the Short Description, then verify Hardware / Projector in the resulting incident. This is the documented Projector test scenario.

DEMONSTRATION SCREEN 6

Screen 6: Projector Test – Final Verification

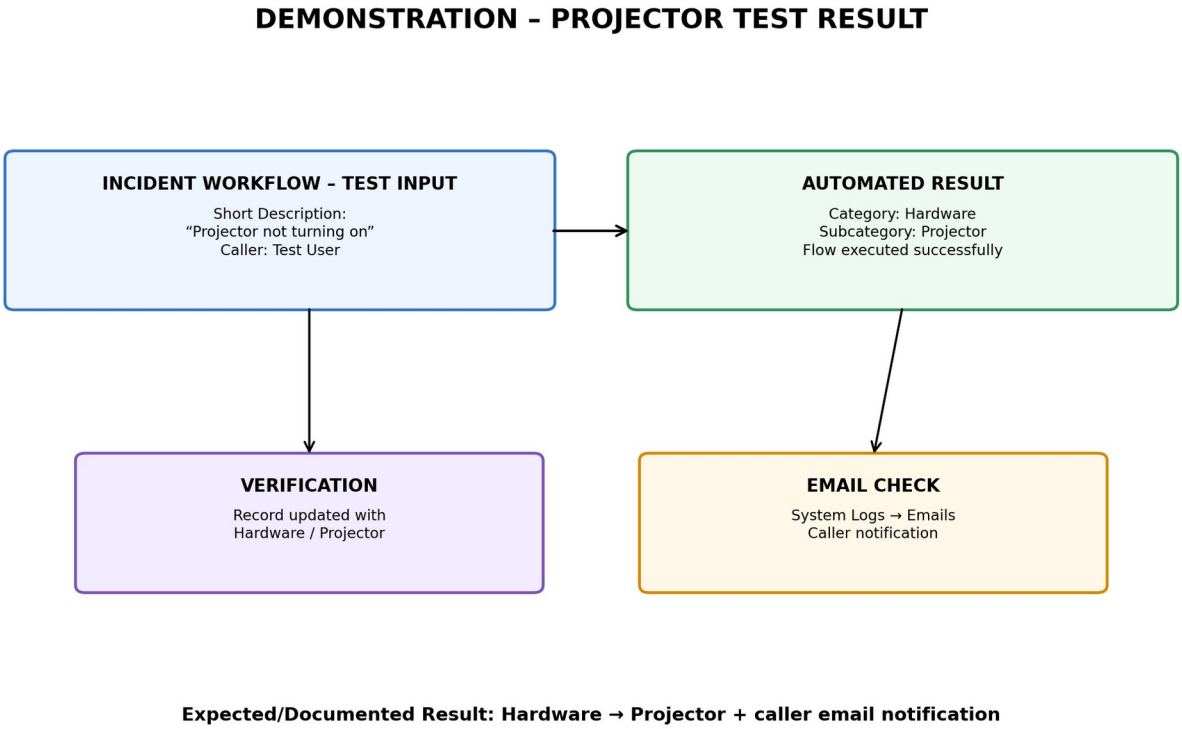

Figure 6: Projector Test – Final Classification and Notification Verification

The final Projector verification confirms that the ticket has been classified as Hardware with Projector as the Subcategory and that the caller notification step can be checked. The demonstration should show the completed record and, where available, the corresponding email evidence.

Final Demonstration Checklist

- Show the Incident Workflow record and Short Description.
- Show the resulting Category and Subcategory.
- Open Flow Designer and show the active classification flow.
- Show the Update Record and Send Email actions.
- Verify the caller notification.
- Demonstrate additional Password/Login and Slow/Hanging branches only after actual execution and evidence.
